NOAA Technical Memorandum NMFS

The National Oceanic and Atmospheric Administration (NOAA) was organized in 1970. It has evolved into an agency which establishes national policies and manages and conserves our oceanic coastal, and atmospheric resources. It provides managerial, research, and technical expertise to produce practical services and essential information for the programs concerned with such resources.

The National Marine Fisheries Service (NMFS) provides the United States with an integrated program of management, research, and services concerned about the protection and rational use of living marine resources for their aesthetic, economic, and recreational value. NMFS determines the consequences of the naturally varying environment and human activities on living marine resources. NMFS provides knowledge and services to foster the efficient and judicious use of those resources. NMFS provides for domestic and for international management and conservation of these living resources of the sea.

To carry out its mission, the organization also provides for communication of NMFS information. In addition to its formal publications, NMFS uses the NOAA Technical Memorandum series for informal scientific and technical publications. These documents are specialized reports that require multiple copies when complete formal review and editorial processing are not appropriate or feasible. The management and control of Technical Memorandums has been delegated to the Research Centers, Regional Offices, and corresponding staff offices within NMFS. Therefore, requests for copies of Technical Memorandums should be sent to the author or to the originating office for the material.

NOAA Technical Memorandum NMFS

This TM series is used for documentation and timely communication of preliminary results, interim reports, or special purpose information, and have not received complete formal review, editorial control, or detailed editing.

INTRODUCTION

Since passage of the Fishery Conservation and Management Act (FCMA), there has been an increasing need for information on the fishing activity of foreign vessels in the U.S. Fishery Conservation Zone (FCZ) and other areas of U.S. interest. A knowledge of foreign catch and fishing effort is essential for analysis of management policies, for appraisal of fishery development potentials, and for planning of fishery surveillance and enforcement activities.

In the case of billfishes, foreign catches in the FCZ are made by tuna longline vessels of Japan, Taiwan, and the Republic of Korea. The vessels usually direct their effort toward tunas and catch billfishes only incidentally.¹ The primary purpose of this report is to summarize available information on the nominal effort and the catch of tunas and billfishes by these foreign longline fleets in the FCZ of the central and western Pacific during the period 1965-77. In addition, the report presents estimates of the effort and tuna catch by Japanese baitboats fishing around Hawaii, Guam, the Northern Marianas, and other U.S. possessions.

In the following section the data sources and their characteristics and limitations are described. Then the data summarization and estimation procedures are discussed. Finally, the tables of resulting catch and effort statistics are presented, and suggestions are given for improving and updating the information.

DATA SOURCES

The estimates of foreign catch and effort were based on a variety of statistical sources. In this section the sources are systematically identified and described. For reference purposes a data set name is assigned to each source (Table 1).

Japanese Tuna Longline Statistics by 1° Square [Data Set D1]

This data set consists of records of Japanese tuna longline nominal effort (hooks fished and days fished) and associated catches of tuna and billfish species (number of fish) by month and 1° square. It covers only those 1° squares in the central and western Pacific overlapping the FCZ in Hawaii, American Samoa, and Guam, and only the years 1971-75. The data are unpublished, and were made available to the National Marine Fisheries Service (NMFS) by the Fisheries Agency of Japan. The data were provided in unraised form; estimates of total catch and effort in each time-area stratum were made by multiplying the sample data by raising factors taken from appropriate issues of "Annual Report of Effort and Catch Statistics by Area on Japanese Tuna Longline Fishery" published by the Fisheries Agency of Japan.

¹Under the FCMA, the U.S. claims jurisdiction over billfishes in the FCZ, but not over tunas.

Japanese Tuna Longline Statistics by 5° Square
[Data Set D2]

This data set consists of the well-known published statistics of monthly catch and effort by Japanese tuna longliners in 5° square areas. It is available throughout the range of the Japanese fleet in the Pacific for 1962-77. The data are published in the reference cited above. The catch and effort totals for a 5° square are equal to the sum of these statistics over all 1° squares in the 5° block, i.e., data set D2 may be considered an aggregation of data set D1. The statistics are published in raised form since 1967, and unraised form for the earlier years.

Taiwanese Tuna Longline Statistics by 5° Square
[Data Set D3]

This data set contains monthly statistics on catch of tunas and billfishes (number of fish and weight of fish) and effort (hooks fished) of Taiwanese high-seas longliners by 5° square throughout the range of the fleet. Data for 1967 through 1977 are available, provided to us by the Taiwan Fisheries Bureau. Unraised sample statistics were provided by Taiwan and then raised. Annual summaries of the unraised statistics and raising factors are published by the Taiwan Fisheries Bureau in "Annual Catch Statistics of Taiwan's Tuna Longline Fishery."

American Samoa Tuna Longline Statistics
[Data Set D4]

This unpublished data set contains the catch (number of fish) and effort (hooks fished and days fished) by sampled Taiwanese, Korean, and Japanese longliners based at Pago Pago and operating primarily in the South Pacific. The statistics are extracted from logbooks of daily fishing activity submitted by vessel captains to the Office of Marine Resources of the Government of American Samoa, and are available for the period 1960 through 1976.² The logbook records give daily effort and catch by species along with the midday position of the vessel. Not all vessels submit logbooks, so raising factors are necessary to project the sample catch and effort to the entire fleet. Computation of raising factors is facilitated by a second set of data for vessels based at Pago Pago. These are the records of cannery landings made available to us by Star-Kist Samoa, Inc. and Van Camp Sea Food Co. They provide direct estimates of the tonnage of fish landed by all vessels, those appearing in the logbook statistics and those not covered in the catch and effort sampling.

Japanese Baitboat Statistics
[Data Set D5]

This data set consists of catch and effort records of the Japanese baitboat fleet operating in the central and western Pacific. Catch (in metric tons) and nominal effort (vessel days) are published annually by

²Data for 1977 and 1978 are available, but are incomplete, so catch and effort estimates are possible only through 1976.

the Fisheries Agency of Japan in "Annual Report of Effort and Catch Statistics by Area, Japanese Skipjack Baitboat Fishery." The published records are given by 1° square and 10-day interval. In our analysis we used summaries by month and 1° square for the years 1970-77. On the average, the baitboat statistics cover about 80% of the actual catch and effort, so we raised the statistics by a factor of 1.25.

PROCEDURES AND ASSUMPTIONS

Boundaries

Figure 1 shows the boundaries we used for computing catch and effort within the FCZ around the Hawaiian Islands, American Samoa, Guam, the Northern Mariana Islands, and the various minor U.S. possessions, e.g., Wake Island, Johnston Atoll, Howland Island, Baker Island, Kingman Reef, Palmyra Island, and Jarvis Island. Boundaries are essentially as given in the Federal Register (vol. 42(44)-7 March 1977; vol. 43(7)-11 January 1978), except that we included Kingman Reef as a U.S. territory, and we assumed straight-line closures around parts of Jarvis Island, Howland Island, and Baker Island. Similarly, we drew a provisional boundary (dashed line) around the northern and northeastern part of the American Samoa FCZ (including Swains Island) and assumed a median-line separation between American Samoa and the Tokelau Islands.

The provisional boundaries drawn here were adopted to provide a basis for catch computations only. They are not to be construed as legal limits, nor do they prejudice any U.S. position regarding disputed claims or jurisdictional conflicts in the Pacific.

In addition to computing catches of tunas and billfishes and nominal effort within each of the 200-mile zones, or within the entire FCZ areas, we also computed these statistics for other more restricted zones around Hawaii, American Samoa, Guam, and the Northern Mariana Islands (Figures 2, 3, and 4). The boundaries adopted in these cases were selected primarily for illustrative purposes, and are not intended to reflect any preference with respect to fishery management policy. For the Hawaiian Islands, the chain was split into the main Hawaiian Islands and the Northwestern Hawaiian Islands (NWHI), with the dividing line at 161°W longitude (between Niihau Island and Nihoa Island). Catches and effort were computed within 50 miles, 100 miles, and 200 miles of the islands in each sector (Figure 2).

In the case of Guam, the Northern Mariana Islands, and American Samoa, a 50-mile zone was drawn and catches and effort were estimated for these zones as well as for the entire FCZ (Figures 3 and 4).

Apportioning

Estimates of nominal effort and the catch of tunas and billfishes were made by adding up the appropriate statistics for all 1° squares or 5° squares, or parts thereof, falling within the boundaries of the area of interest. In instances where the boundary of an area cut through a square, the distribution of catch and effort within the square was assumed to be homogeneous, and a part of the square's catch and effort was added to the area totals according to the proportion of the square falling within the area boundaries.

One-degree square statistics (D5) were used to estimate effort and catch of Japanese baitboat vessels around the Hawaiian Islands, Guam, and the Northern Marianas, and other U.S. possessions. One-degree square data were also used for Japanese longline catch and effort around Hawaii and Guam during 1971-75 (D1), and for all of the American Samoa longline catch and effort estimates (D4). In every other case 5° square statistics were used.

Raising Factors

The tuna longline fishery statistical systems of Japan and Taiwan are sampling systems, which means that there is not a complete enumeration or accounting of the catch and effort. Instead, only a sample of the logbooks from vessels operating in the Pacific is covered. The sample catch and effort statistics must be expanded to produce estimates of total catch and effort, using raising factors. Sampling coverage for Japanese tuna longline vessels is relatively high (Table 2). Coverage is proportional to size of the vessel for Japan-based boats. The raising factors for Japanese statistics are available only on an annual and Pacific-wide basis.

In the case of Taiwanese longliners, raising factors are available monthly (Table 3), but for all sizes of vessels combined and for the entire Pacific until 1977. Beginning in 1977, factors were computed by month and 5° square. Coverage of Taiwanese vessels is very low, being generally less than 20%.

For vessels based at Pago Pago, coverage is variable. From 50 to 95% of the vessels landing at Pago Pago submit logbooks containing detailed statistics on catch and effort. Since 1970 Korean vessels have been covered more completely than longliners from Taiwan, and for vessels of both flags the coverage rate has decreased considerably from the levels maintained during the 1960's.

In our initial analyses we computed raising factors for American Samoa as the product of (1) estimated average weight, taken from Taiwanese longline data for the area, and (2) ratio of landings by all vessels to landings by those vessels included in the logbook sampling. However, when these factors were applied to the sampled numerical catches the resulting estimates of total catch in weight were in most cases less than the recorded total cannery landings. This could happen if our average weight estimates were too low, or the proportion of the catch actually landed and recorded in cannery records was greater for sampled longliners [those submitting logbooks] than for other vessels, or the logbook catch data for sampled vessels was incomplete. Since no detailed information was available for evaluating these possible sources of error, we carried out the catch and effort estimation in a different manner. First we adjusted the billfish landings during each quarter to account for billfish which were landed at one of the canneries but did not appear in the statistics available to us. This adjustment was made assuming the ratio of billfish landings to tuna landings was the same at the two canneries. It was done separately for each vessel nationality. Next, the adjusted landings were multiplied by other correction factors to convert from dressed weights to round weights. These correction factors were 1.15 for yellowfin tuna, 1.16 for bigeye tuna, 1.2 for billfishes, and 1.0 for albacore and wahoo. Then, final correction factors were

computed by year, species (except billfishes were combined), nationality, and cannery as the ratios of total landings (adjusted as indicated above) to the corresponding total numbers of fish caught by the sampled vessels. These final factors were multiplied by the individual monthly catches in 1° cells (D4) and, after apportioning in the manner described above, the products were summed within each zone of interest. This procedure was followed for billfishes, albacore, yellowfin, bigeye, and wahoo. Thus for these species we assumed the total adjusted cannery landings were accurate and accounted for all fish caught. The remaining species are skipjack and bluefin tunas. These are very minor constituents of the catch and are neglected in the canneries' summary statistics. Therefore, for these species we estimated total catches in weight by simply multiplying the observed catches in number of fish by estimated average weights of 6.0 kg (skipjack tuna) and 52.6 kg (bluefin tuna).

The cannery statistics should account for virtually all tuna and billfish taken by the longliners based at Pago Pago, although small amounts which are not landed there may go unrecorded.

Adjustment factors were also used to estimate the total nominal fishing effort by American Samoa longliners. These were computed by nation, cannery, and year as the ratio of total vessel days of fishing by all vessels covered in the statistics of cannery landings to the number of vessel days fished by longliners appearing in the logbook sampling.

As mentioned in an earlier section, a raising factor of 1.25 was used to expand the sample Japanese baitboat catch and effort statistics.

Average Weights

The basic longline catch statistics of data sets D1, D2, D3, and D4 are expressed in number of fish taken. (Weight of catch is also reported by Taiwanese longliners (data set D3), but this information was available to us only in aggregate form.)

Longline catches in weight for Hawaii, Guam, the Northern Marianas, and minor U.S. possessions were estimated by multiplying catch in number by appropriate values of average weight. The average weight statistics came from two sources:

- (1) Average weights for catches in the Hawaiian FCZ and around Johnston Atoll were based on annual statistics from the Hawaiian domestic longline fleet, provided by the United Fishing Agency, Ltd. of Honolulu, Hawaii and the Hawaii Division of Fish and Game (Table 4).
- (2) The average weights of tunas and billfishes taken elsewhere by longliners of Taiwan and Japan were estimated from data obtained from the Fisheries Agency of Japan and from publications of the Taiwan Fisheries Bureau (Table 5).

Accuracy

Assuming the basic statistics we used are correct, the accuracy and reliability of our catch and effort estimates depend on two main conditions: (1) homogeneity of catch and effort distribution within the smallest space-time stratum under consideration, and (2) uniformity of sample coverage in time and space.

The first condition does not generally hold, as may be demonstrated by comparing estimates based on 5° square data with corresponding estimates based on 1° square statistics. A 5° breakdown of catch and effort statistics is simply too coarse for an accurate, detailed spatial analysis of fishing activity within the FCZ. Estimates based solely on 5° square data should therefore be viewed circumspectly.

Even greater problems are created by departures from the second condition. The use of a common ocean-wide raising factor may be perfectly adequate for ocean-wide estimates, but may lead to serious distortion in estimates of catch and fishing effort in small subareas of the ocean. Steps have recently been taken by the Taiwan Fisheries Bureau to improve their sampling system so that individual raising factors are available by month and 5° square.

Considering these factors, it is obvious that one cannot put a great deal of confidence in some of the catch and effort estimates. Nevertheless, these estimates are the best currently available.³

THE CATCH AND EFFORT TABLES

The estimated nominal effort and catch statistics are presented in Tables 6 through 91. Catches are stated in metric tons (mt). Effort is given in vessel days. In the case of Taiwan longline effort outside the American Samoa area, the effort figures were estimated by dividing the number of hooks fished by 2,000, which is approximately the average number of hooks fished per vessel day. In other cases effort was computed directly. An asterisk in the effort section denotes effort greater than zero but less than 1 vessel day. An asterisk in the catch columns means some fish were caught but less than 1 mt.

³A similar report has been released by the South Pacific Commission, Noumea, New Caledonia. See: Klawe, W. L. 1978. Estimates of catches of tunas and billfishes by the Japanese, Korean, and Taiwanese longliners from within the 200-mile economic zone of the member countries of the South Pacific Commission; SPC Occasional Paper No. 10

Longline catch estimates are presented for the following species:

albacore	<u>Thunnus alalunga</u>
yellowfin tuna	<u>T. albacares</u>
bigeye tuna	<u>T. obesus</u>
bluefin tuna ⁴	<u>T. thynnus</u>
skipjack tuna	<u>Katsuwonus pelamis</u>
blue marlin	<u>Makaira nigricans</u>
black marlin	<u>M. indica</u>
striped marlin	<u>Tetrapturus audax</u>
swordfish	<u>Xiphias gladius</u>
sailfish	<u>Istiophorus platypterus</u>
shortbill spearfish	<u>T. angustirostris</u>

In addition, catches of wahoo, Acanthocybium solandri, are given for the longline vessels based at Pago Pago. Note that all tables of longline catches give a combined estimate of the catch of sailfish and shortbill spearfish, since these species are not separated in the records submitted by either Japanese or Taiwanese longline fishermen, or in the logbook records of foreign vessels based at American Samoa.

The Japanese baitboat catch estimates are given for albacore, yellowfin, bigeye, bluefin, and skipjack. In addition, catches of frigate tuna, Auxis thazard, and miscellaneous species (others) are estimated.

IMPROVING ESTIMATES

We have identified several possible shortcomings in the estimates of catch and effort within specified geographical areas. The estimates may be improved by (1) using more detailed longline statistics than the usual 5° square summaries which are now generally available. In the case of longline vessels based at Pago Pago daily fishing logs are available to us. But the official, published longline statistics of Taiwan, Japan, and Korea are only by 5° square. More detailed Japanese data are available in unpublished form; (2) using more detailed raising factors, instead of the Pacific-wide factors now employed. Taiwan has taken steps to refine this aspect of their longline catch estimation--it would be useful if other nations also instituted such improvements; (3) using more accurate statistics on average weight. Temporal and spatial variation should be taken into account, and better size statistics should be sought from unpublished sources; (4) a more complete analysis of the American Samoa-based fishery. The estimates given here reflect only the landings reported by the two tuna canneries operating in Pago Pago. The records available to us do not take into account small amounts of fish landed and sold through other channels. A more extensive study of American Samoa fishery statistics should be undertaken so that a complete accounting can be made of all fish caught or landed in that area of the FCZ.

⁴In the case of vessels based at American Samoa, the negligible bluefin catch is mostly southern bluefin tuna (T. maccoyii) taken in the southern extremity of the South Pacific albacore grounds.

The estimates reported here do not present a complete picture of foreign tuna and billfish catches in the FCZ, since except for American Samoa-based vessels no Korean statistics were considered. Korean tuna longliners (mostly sashimi boats) are known to fish in all areas of the FCZ, and while extensive catch and effort data are available, we are not yet able to answer key questions about appropriate raising factors, sampling procedures, and reliability. Until such considerations can be dealt with, we will refrain from using the Korean longline statistics.

In addition to problems with the Korean longline statistics we have been unable to evaluate possible Korean baitboat catches in the FCZ. No information is available to us on this subject.

Mention should be made of fishing inside the Hawaii FCZ by longline vessels based in American Samoa. Such catches, mainly by Korean boats, are minor, but the frequency of such visits has been increasing in recent years. Information on this subject is being compiled for publication in a separate report.

A comment is also needed concerning the possibility that some small catch in the American Samoa FCZ is made by longliners not based in Pago Pago and therefore not monitored in the American Samoa logbook system. Catches by Japanese vessels can be ruled out, since Japanese Government statistics show no effort in that area by her vessels since 1971. But the question remains unanswered for Taiwan and Korea.

Finally, the published catch and effort records examined in this analysis do not cover any Japanese baitboats or longliners under 20 gross tons, or any Taiwanese longliners under 50 gross tons. This is of no consequence except around Guam and the Northern Marianas, where some small Taiwan-based Taiwanese longliners and small Japanese longliners may be operating. Also neglected are any Japanese purse seine catches of tunas in this area; however, these are negligible, as most purse seine activity is south of this region.
